DESCRIPTION (CONTINUED)

The Lyons Ferry Bridge is a rather late example of the once common practice of reusing a truss at different locations. Part of the merit of the truss lies in the versatility and economy of its design. Because of the standardization of its parts, it can be easily rebuilt to fit the dimensions of several crossings during its lifetime.

The Snake River Bridge is representative of the cantilever truss, a truss form used in the construction of long span bridges. It is significant as part of the major construction of long-span highway bridges that occurred in Washington State during the 20's. And it is significant in the manner in which it demonstrates the flexibility and wersatility of the long span truss, and its capabilities in serving more than one crossing.

DESCRIBE THE PRESENT AND ORIGINAL (IF KNOWN) PHYSICAL APPEARANCE

Over a period of several million years, basalt flows covered much of south-central as south-eastern Washington State. In some areas, drilling revealed depths of over 10,000 feet and still the extent of lava had not been reached. Soil which subsequent covered much of the basalt was stripped from the land during a series of catastrophic floods, the last of which was extimated to have occurred some 12,000 years ago. Much of the land has a barren, dry, isolated, "other-world" feeling. The scablands of eastern Washington are, in fact, a unique geologic formation.

The Snake River, at the Lyons Ferry Crossing, has cut through over one thousand feet of successive layers of basalt, leaving rugged cliffs and benches framing the river. The Palouse River joins the Snake immediately upstream of the crossing site and also has cut a deep canyon about nine miles back from the confluence, producing a spectacular waterfall of one hundred and ninety-eight feet, higher than Niagara Falls.

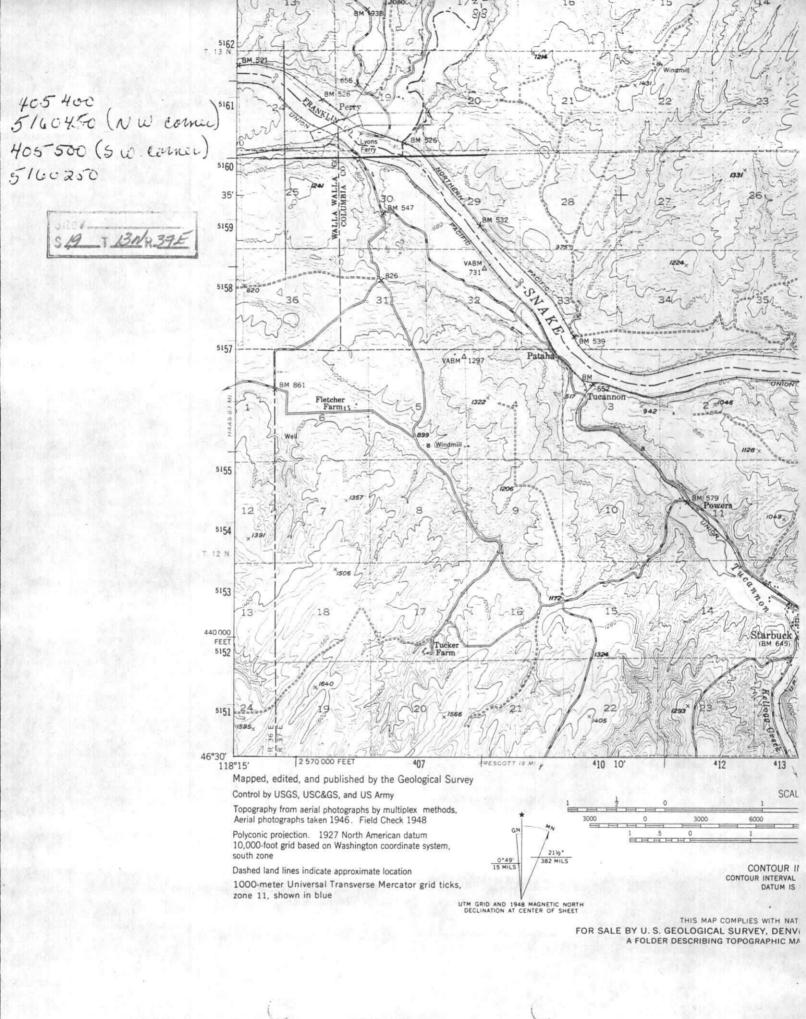

The site is located in a region with hot and dry summers and cool and dry winters.

Where there are not coulees and lava outcrops, dryland farming can be practiced. Livestock also graze in the region. There are semi-active sand dunes and blowouts nearby. The immediate area as well as the surrounding countryside is treeless and rocky. Sagebrush and rattlesnakes abound. Marmes Rockshelter, a listing in the National Register of Historic Places, is about two and one half miles up the Palouse River. Aerial photographs show a rugged disected topography along the river with little habitation. Population density is almost two persons per square mile.

With the completion of Lower Monumental Lock and Dam a lake, less than one-half mile in width, has been created which covers the ferry slips. State Highway 261, just upstream from the ferry landing, crosses the Snake at Lyons Ferry, the first highway from the confluence of the Snake and Columbia Rivers to bridge the former stream. The Union Pacific Railroad Joso Bridge is immediately downstream from the former ferry landing. It appears that the Mullan Road crossed the Snake closer to the location of the railroad bridge.

Recreation facilities have been developed in recent years with the creation of Lyons Ferry State Park at the meeting of the Palouse and Snake Rivers. The Palouse River Canyon, a natural area of high scenic quality and wildlife values which rextends northward from the Snake River, has been reserved for intensive wildlife management.

Although the bridges and the State Park are intrusions on the topography, their appearance is obviously of structures superimposed on a timeless landscape which for all intents and purposes is as it was for hundreds if not thousands of years into the past. The basic geology of the region has changed little in the past 12,000 years and looks very much as it did when the native peoples crossed Snake River at the mouth of the Palouse.

Historic Register Report

Historic Name: Snake River Bridge

(Lyons Ferry)

Address: North of SR 12

City: Lyons Ferry County: Columbia
